

The seismic consequences of being a leaky fault

Gaspard Farge

University of California Santa Cruz

In collaboration with:

Emily Brodsky — UC Santa Cruz

Nikolai Shapiro — ISTerre (Grenoble)

Claude Jaupart — IPGP (Paris)

Tremor indicates a fast stress release process on (near) the plate interface

Tremor activity is “synchronized”

Segmentation of tectonic tremor in the Cascadia subduction zone

Adapted from Wech et al. (2021, 2008 etc)

i.e. Large portions of the fault activate at the same time

➔ Characteristic sizes

➔ Periodicity

Tremor is generated as the fault **slips slowly**, in a **high fluid pressure environment**

Tremor and slip under Vancouver Island

Geodetically-detected slow slip

LFE focal mechanism (Nankai, Japan)

Modified from Ide et al. (2007)

Faster, localized slip becomes seismic

Strong, fast (?) fluid pressure transients

A fault-valve mechanism

Hydraulic and **solid** stresses load the fault simultaneously

Hydraulic loading

Solid stress loading

$$\text{Stress to failure: } F = \mu\sigma_n - (\mu p(t) - \tau(t))$$

$$\text{Stress loading: } L(t) = \mu p(t) + \tau(t)$$

$*F_0$: Residual fault strength after failure
($F_0 = \mu\sigma_n$ for full stress drop)

A fault-valve mechanism

Hydraulic and **solid** stresses load the fault simultaneously

$$\text{Stress loading: } L(t) = \boxed{\mu p(t)} + \boxed{\tau(t)}$$

The dynamics of stress accumulation has fundamental consequences on the seismic cycle

$*F_0$: **Solid**+**Hydraulic** strength

Stresses leak out of the fault

Hydraulic stresses leak out of the fault due to (*low*) **permeability seals**

Leaking flux

$$q(t) = K (p(t) - p_0)$$

Pressure increase through fluid storage

$$\dot{p} = Q/S$$

Hydraulic stress loading:

$$\dot{p}(t) = \frac{Q}{S} - \frac{K}{S} p(t) + \text{cst}$$

Elastic fluid storage

Q : dehydration flux
 S : storativity

Permeability leak

K : seal conductivity

Stresses leak out of the fault

Hydraulic and **solid** stresses both leak out of the fault producing a concave loading curve in time

$$\text{Stress loading: } L(t) = \boxed{\mu p(t)} + \boxed{\tau(t)}$$

$$\text{Hydraulic loading: } \dot{p}(t) = \frac{Q}{S} - \frac{K}{S} p(t)$$

$$\text{Solid loading: } \dot{\tau}(t) = GV - \frac{G}{\eta_s} \tau(t)$$

- ➡ **Leakage competes with steady loading in shaping the recurrence**
- ➡ **The curvature makes the stress sit near failure for a long share of the cycle**

The seismic consequences of being a leaky fault

- 1. Sources and sinks control recurrence**
- 2. Tremor synchronization**
- 3. Sensitivity to transients**

Segmentation of ETS recurrence along-strike

Synchronization emerges from interactions between fault segments

- ➡ Synchronization through **constructive stress interactions**: failure brings neighbors closer to fail
- ➡ Synchronization in time/space translates into **regularity of recurrence**

Synchronization emerges from interactions between fault segments

Modeling interactions in a purely hydraulically loaded fault

Modeling results from Farge et al. (2021, 2023)

Valve mechanism

A 1D permeable channel,
saturated with fluid

The proximity to rupture controls sensitivity to interactions

The source **source flux** Q shapes the cycle of a fault element:

- ➡ How **close to threshold** it is on average
- ➡ How **sensitive** to neighboring activity

The proximity to rupture controls sensitivity to interactions

The source **source flux** Q shapes the cycle of a fault element:

- ➡ How **close to threshold** it is on average
- ➡ How **sensitive** to neighboring activity

High Q : short-range synchronization

Low Q : long-range synchronization

Segmentation of ETS synchronization along-strike

➡ *Lower source flux Q / higher sink conductivity K produces more efficient interactions, thus more synchronized activity*

The seismic consequences of being a leaky fault

1. Sources and sinks control recurrence
2. Tremor synchronization
3. Sensitivity to transients

Triggers?

Earthquakes trigger tremor

- Large earthquakes known to trigger tremor globally and regionally

Small Earthquakes trigger tremor

- Large earthquakes known to trigger tremor globally and regionally
- ***Smaller earthquakes trigger tremor locally***

Tremor is extremely* sensitive to dynamic stress

The same dynamic stress produces ~ **x100 more triggering of LFEs than EQ*

Tremor is extremely* sensitive to dynamic stress

*Tremor /
slow-slip
loading*

*Earthquake
loading*

**The same dynamic stress
produces ~ **x100 more**
triggering of LFEs than EQ*

Consequences for tremor synchronization

How far along-strike is the activity correlated, and do earthquakes influence it?

⋈ Tremor (NIED, Maeda et al, 2009, Obara et al, 2010)

Consequences for tremor synchronization

How far along-strike is the activity correlated, and do earthquakes influence it?

⋯ Tremor (NIED, Maeda et al, 2009, Obara et al, 2010)

⋯ Earthquakes (JMA, $M > 2.2$, $< 50\text{km}$ from tremor)

Nankai tremor

Tokai

Kii

Shikoku

In 7 tremor zones across the world

1. Measure tremor correlation length

Japan Trench

- Nishikawa et al (2023) tremor
- JMA earthquakes
- 6.5 years, 1000 km

Nankai

- NIED tremor
- JMA earthquakes
- 21 years, 700 km

Cascadia

- PNSN tremor
- ComCat earthquakes
- 15 years, 1,200 km

2. Measure number of earthquakes “felt” by tremor

Alaska

- Wech (2016) tremor
- ComCat earthquakes
- 3 years, 350 km

Taiwan

- Ide & Chen (2024) tremor
- CWASN earthquakes
- 11 years, 350 km

Hikurangi

- Todd & Schwartz (2016) tremor
- GeoNet earthquakes
- 7 years, 160 km

Parkfield

- Shelly (2017) LFEs
- Waldhauser & Schaff (2008) earthquakes
- 17 years, 160 km

Small earthquake activity anti-correlates with tremor synchronization

Across regions and along strike

Small Earthquakes Disrupt Tectonic Tremor Synchronization

Interactions through rupture synchronize fault activity in time and space

Cascadia tremor and earthquakes

Interactions through rupture synchronize fault activity in time and space

Interactions through rupture synchronize fault activity in time and space

Cascadia tremor and earthquakes

Interactions through rupture synchronize fault activity in time and space

Interactions through rupture synchronize fault activity in time and space

Local earthquakes disturb the synchronization process and inhibit the emergence of large ruptures

***Small earthquakes
= local effects***

Small earthquakes disrupt tectonic tremor synchronization

➡ Can be modeled!

$$\frac{d\sigma}{dt} = V - \alpha\sigma$$

From Farge & Brodsky (2025) – The big impact of small quakes on tremor synchronization (Sci. Adv.)

Conclusion

The extraordinary synchronization and sensitivity of tremor and slow slip could emerge from stress leakage

$$\frac{d\sigma}{dt} = V - \alpha\sigma$$
